

## RSA Algorithm with Numerical Example

1. Select two prime numbers,  $p = 17$  and  $q = 11$ .
2. Calculate  $n = pq = 17 \times 11 = 187$ .
3. Calculate  $\phi(n) = (p - 1)(q - 1) = 16 \times 10 = 160$ .
4. Select  $e$  such that  $e$  is relatively prime to  $\phi(n) = 160$  and less than  $\phi(n)$ ; we choose  $e = 7$ .
5. Determine  $d$  such that  $de \equiv 1 \pmod{160}$  and  $d < 160$ . The correct value is  $d = 23$ , because  $23 \times 7 = 161 = (1 \times 160) + 1$ ;  $d$  can be calculated using the extended Euclid's algorithm (Chapter 2).

The resulting keys are public key  $PU = \{7, 187\}$  and private key  $PR = \{23, 187\}$ . The example shows the use of these keys for a plaintext input of  $M = 88$ . For encryption, we need to calculate  $C = 88^7 \pmod{187}$ . Exploiting the properties of modular arithmetic, we can do this as follows.

$$88^7 \pmod{187} = [(88^4 \pmod{187}) \times (88^2 \pmod{187}) \times (88^1 \pmod{187})] \pmod{187}$$

$$88^1 \pmod{187} = 88$$

$$88^2 \pmod{187} = 7744 \pmod{187} = 77$$

$$88^4 \pmod{187} = 59,969,536 \pmod{187} = 132$$

$$88^7 \pmod{187} = (88 \times 77 \times 132) \pmod{187} = 894,432 \pmod{187} = 11$$

For decryption, we calculate  $M = 11^{23} \pmod{187}$ :

$$11^{23} \pmod{187} = [(11^1 \pmod{187}) \times (11^2 \pmod{187}) \times (11^4 \pmod{187}) \times (11^8 \pmod{187}) \times (11^8 \pmod{187})] \pmod{187}$$

$$11^1 \pmod{187} = 11$$

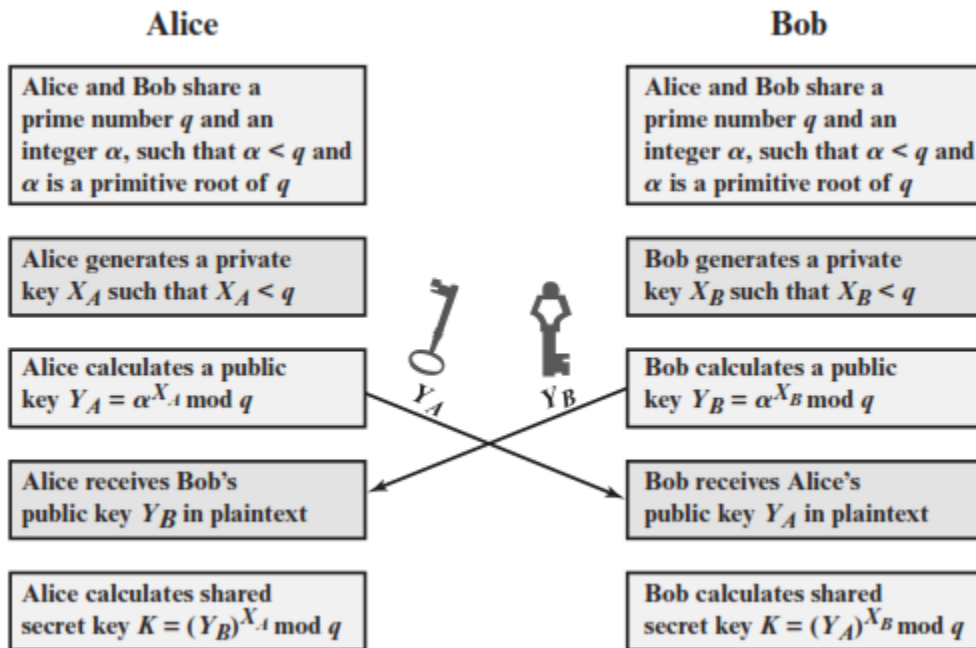

$$11^2 \pmod{187} = 121$$

$$11^4 \pmod{187} = 14,641 \pmod{187} = 55$$

$$11^8 \pmod{187} = 214,358,881 \pmod{187} = 33$$

$$\begin{aligned} 11^{23} \pmod{187} &= (11 \times 121 \times 55 \times 33 \times 33) \pmod{187} \\ &= 79,720,245 \pmod{187} = 88 \end{aligned}$$

## Diffie Hellman Key Exchange

Here is an example. Key exchange is based on the use of the prime number  $q = 353$  and a primitive root of 353, in this case  $\alpha = 3$ . A and B select private keys  $X_A = 97$  and  $X_B = 233$ , respectively. Each computes its public key:

A computes  $Y_A = 3^{97} \bmod 353 = 40$ .

B computes  $Y_B = 3^{233} \bmod 353 = 248$ .

After they exchange public keys, each can compute the common secret key:

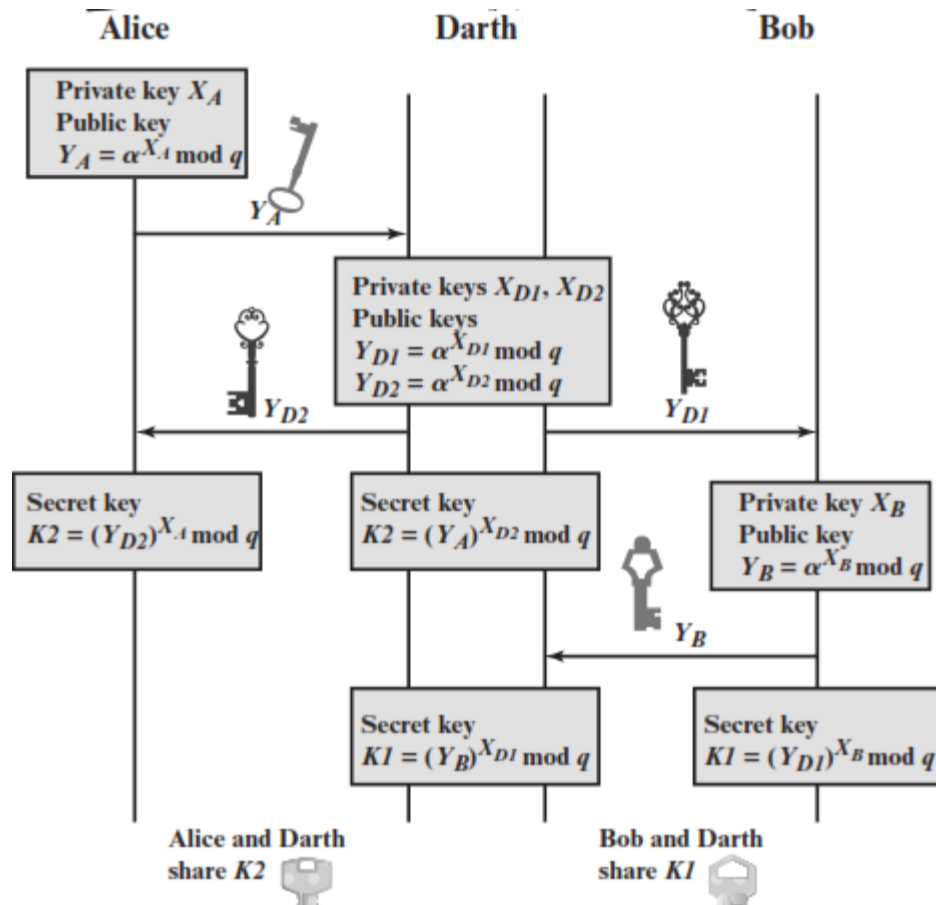

A computes  $K = (Y_B)^{X_A} \bmod 353 = 248^{97} \bmod 353 = 160$ .

B computes  $K = (Y_A)^{X_B} \bmod 353 = 40^{233} \bmod 353 = 160$ .

We assume an attacker would have available the following information:

$$q = 353; \alpha = 3; Y_A = 40; Y_B = 248$$

## Man in the Middle Attack

## ELGAMAL CRYPTOGRAPHIC SYSTEM

The global elements of Elgamal are a prime number  $q$  and  $\alpha$ , which is a primitive root of  $q$ . User A generates a private/public key pair as follows:

1. Generate a random integer  $X_A$ , such that  $1 < X_A < q - 1$ .
2. Compute  $Y_A = \alpha^{X_A} \bmod q$ .
3. A's private key is  $X_A$  and A's public key is  $\{q, \alpha, Y_A\}$ .

Any user B that has access to A's public key can encrypt a message as follows:

1. Represent the message as an integer  $M$  in the range  $0 \leq M \leq q - 1$ . Longer messages are sent as a sequence of blocks, with each block being an integer less than  $q$ .
2. Choose a random integer  $k$  such that  $1 \leq k \leq q - 1$ .
3. Compute a one-time key  $K = (Y_A)^k \bmod q$ .
4. Encrypt  $M$  as the pair of integers  $(C_1, C_2)$  where

$$C_1 = \alpha^k \bmod q; C_2 = KM \bmod q$$

User A recovers the plaintext as follows:

1. Recover the key by computing  $K = (C_1)^{X_A} \bmod q$ .
2. Compute  $M = (C_2 K^{-1}) \bmod q$ .

### Example:

1. Alice chooses  $X_A = 5$ .
2. Then  $Y_A = \alpha^{X_A} \bmod q = \alpha^5 \bmod 19 = 3$  (see Table 2.7).
3. Alice's private key is 5 and Alice's public key is  $\{q, \alpha, Y_A\} = \{19, 10, 3\}$ .

Suppose Bob wants to send the message with the value  $M = 17$ . Then:

1. Bob chooses  $k = 6$ .
2. Then  $K = (Y_A)^k \bmod q = 3^6 \bmod 19 = 729 \bmod 19 = 7$ .
3. So
 
$$C_1 = \alpha^k \bmod q = \alpha^6 \bmod 19 = 11$$

$$C_2 = KM \bmod q = 7 \times 17 \bmod 19 = 119 \bmod 19 = 5$$
4. Bob sends the ciphertext (11, 5).

For decryption:

1. Alice calculates  $K = (C_1)^{X_A} \bmod q = 11^5 \bmod 19 = 161051 \bmod 19 = 7$ .
2. Then  $K^{-1}$  in GF(19) is  $7^{-1} \bmod 19 = 11$ .
3. Finally,  $M = (C_2 K^{-1}) \bmod q = 5 \times 11 \bmod 19 = 55 \bmod 19 = 17$ .

### RSA Based Digital Signature

RSA based digital Signature

Suppose  $p=5, q=7$

$n=5 \times 7 = 35$

$(n)=(p-1) \times (q-1) = 4 \times 6 = 24$

Now, choose  $e$  between 1 and  $n$   
 $e$  should be relative prime to  $n$

Suppose,  $e = 13$

now choose  $d$  such that  $ed \equiv 1 \bmod n$

$$13d \equiv 1 \bmod 24$$

**$d = 37$**

**$e$  is public while  $d$  is private**

Suppose message hash i.e.  $H(M) = 3$

Now, Digital signature is computed as

$$= m^d \bmod n = 3^{37} \bmod 35 = \mathbf{3}$$

Signature Verification

$m =$

$$= 3^{13} \bmod 35 = \mathbf{3}$$
